Problem 1a

Sum of inifnite series.

$$\sum_{t=0}^{\infty} \gamma^t r_t = \frac{-2}{1-\gamma}$$

Problem 1b

The optimal policy depends on the value of γ because a very small γ will disregard the +5 reward in later time steps but a large γ might favor it. The two sum of rewards is the following for the action pairs (go, go) and (stay, don't care) respectively.

$$\pi_a = (\text{go, go}) \rightarrow V = 5\gamma - 3$$

$$\pi_b = (\text{stay, go/stay}) \rightarrow V = \frac{-2}{1-\gamma}$$

To find the optimal policy, we find which reward is larger based on the value of γ. If $\frac{4+\sqrt{11}}{5} < \gamma < 1$ then choose policy a. If $\gamma < \frac{4+\sqrt{11}}{5}$ then choose policy b.

Problem 1c

$$V(s) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \rightarrow \begin{bmatrix} -2 \\ 5 \end{bmatrix} \rightarrow \begin{bmatrix} \max(-2-2, 5-3) = 2 \\ \max(-2+5, 5) = 5 \end{bmatrix} \rightarrow \begin{bmatrix} \max(-2-2, 5-3) = 2 \\ \max(-2+5, 5) = 5 \end{bmatrix}$$

Problem 2a

$$||V^1 - V^*|| = || \begin{bmatrix} -2 \\ 5 \end{bmatrix} - \begin{bmatrix} 2 \\ 5 \end{bmatrix} || = 4$$

$$||V^2 - V^*|| = || \begin{bmatrix} 2 \\ 5 \end{bmatrix} - \begin{bmatrix} 2 \\ 5 \end{bmatrix} || = 0$$

$$||V^3 - V^*|| = || \begin{bmatrix} 2 \\ 5 \end{bmatrix} - \begin{bmatrix} 2 \\ 5 \end{bmatrix} || = 0$$

Problem 2b

First we can show the difference between $T(V)$ and $T(V')$.

Proof.

$$T(V) - T(V') = \max_a \sum_{s'} p(s'|s,a)[r(s,a) + \gamma V(s')] - \max_a \sum_{s'} p(s'|s,a)[r(s,a) + \gamma V'(s')]$$

Because we are summing over all probabilities, we can remove the reward factor.

$$T(V) - T(V') = \max_a \left(r(s,a) + \sum_{s'} p(s'|s,a)[\gamma V(s')] \right) - \max_a \left(r(s,a) + \sum_{s'} p(s'|s,a)[\gamma V'(s')] \right)$$

$$||T(V) - T(V')||_\infty = || \max_a \left(r(s,a) + \sum_{s'} p(s'|s,a)[\gamma V(s')] \right) - \max_a \left(r(s,a) + \sum_{s'} p(s'|s,a)[\gamma V'(s')] \right) ||_\infty$$

We can remove the double max function because the difference of max is always less than the max of differences.

$$||T(V) - T(V')||_\infty \leq || \max_a \left(\sum_{s'} p(s'|s,a)[\gamma V(s')] - \sum_{s'} p(s'|s,a)[\gamma V'(s')] \right) ||_\infty$$

$$||T(V) - T(V')||_\infty \leq || \max_a \left(\sum_{s'} p(s'|s,a)(\gamma V(s') - \gamma V'(s')) \right) ||_\infty$$

Because we are taking the infinity norm over the state space, we can remove the sum over s' from the value iteration.

$$||T(V) - T(V')||_\infty \leq ||(\gamma V(s') - \gamma V'(s'))||_\infty \cdot || \max_a \left(\sum_{s'} p(s'|s,a) \right) ||_\infty$$

The second sum term is again a sum over all probabilities so we can remove it as it is 1.

$$||T(V) - T(V')||_\infty \leq ||(\gamma V(s') - \gamma V'(s'))||_\infty$$

$$||T(V) - T(V')||_\infty \leq \gamma ||V(s') - V'(s'))||_\infty$$

Problem 2c

extra credit

Problem 2d

extra credit

Problem 3a

extra credit

Problem 3b

extra credit

Problem 3c

extra credit

Problem 3d

extra credit

Problem 4a

Proof. $\nabla_\theta J(\theta) = \nabla_\theta \mathbb{E}[\mathcal{R}(\tau) - b] = \nabla_\theta \mathbb{E}[\mathcal{R}(\tau)] = \nabla_\theta \mathbb{E}[\mathcal{R}'(\tau)]$

$$\nabla_\theta J(\theta) = \mathbb{E}[\mathcal{R}(\tau) \nabla \log \pi_\theta(\tau) - b \nabla \log \pi_\theta(\tau)]$$

$$\nabla_\theta J(\theta) = \mathbb{E}[\mathcal{R}(\tau) \nabla \log \pi_\theta(\tau)] - \mathbb{E}[b \nabla \log \pi_\theta(\tau)]$$

The expectation over $\pi(\tau)$ is a constant because it does not depend on τ and only θ. Thus, when we take the gradient of a constant, we get 0.

$$\mathbb{E}[b \nabla \log \pi_\theta(\tau)] = 0$$

So,

$$\nabla_\theta J(\theta) = \nabla_\theta \mathbb{E}[\mathcal{R}(\tau) - b] = \nabla_\theta \mathbb{E}[\mathcal{R}(\tau)] = \nabla_\theta \mathbb{E}[\mathcal{R}'(\tau)]$$

□

Problem 4b

$$\text{Var}\left(\nabla J(\theta)\right) = \mathbb{E}\left[\nabla J(\theta)^2\right] - \mathbb{E}\left[\nabla J(\theta)\right]^2$$

Dependance on b is 0 in the right most expectation so we leave it out.

$$\text{Var}\left(\nabla J(\theta)\right) = \mathbb{E}\left[((\mathcal{R}(\tau) - b)\nabla \log \pi)^2\right] - \mathbb{E}\left[\mathcal{R}(\tau)\nabla \log \pi\right]^2$$

$$\text{Var}\left(\nabla J(\theta)\right) = \mathbb{E}\left[(\mathcal{R}(\tau)\nabla \log \pi)^2\right] - 2b\mathbb{E}\left[\mathcal{R}(\tau)(\nabla \log \pi)^2\right] + b^2\mathbb{E}\left[(\nabla \log \pi)^2\right] - \mathbb{E}\left[\mathcal{R}(\tau)\nabla \log \pi\right]^2$$

$$\text{Var}\left(\nabla J(\theta)\right) = \mathbb{E}\left[(\mathcal{R}(\tau)\nabla \log \pi)^2\right] - 2b\mathbb{E}\left[\mathcal{R}(\tau)(\nabla \log \pi)^2\right] + b^2 - \mathbb{E}\left[\mathcal{R}(\tau)\nabla \log \pi\right]^2$$

Now we take the derivative with respect to b and set to 0.

$$0 = -2\mathbb{E}\left[\mathcal{R}(\tau)(\nabla \log \pi)^2\right] + 2b$$

$$\hat{b} = \mathbb{E}\left[\mathcal{R}(\tau)(\nabla \log \pi)^2\right]$$

Problem 5

Summarize and Key Findings

First, let me say that the notation in this paper is very annoying. How am I suppose to pronounce ꓤꓤ? This is, by far, the greatest weakness of this paper because I spent ten minutes deciding on what to call it.
Anyway, this paper proposes a method for combining reinforcement learning and supervised learning. This is not typical because, as the paper says, incorrect action in supervised learning is an error but in reinforcement learning, incorrect action is an evaluation measure. Additionally, in supervised learning, all pieces of data are i.i.d. but this assumption is broken in reinforcement learning as data (states) are only observed when they are reached which might not happen. The paper proposes a method to observe state action pairs and use the reward as an input to the algorithm. This method seems eerily similar to imitation learning where behavioral cloning is the end goal. In reinforcement learning, the agent will choose an action based on the expected reward and will enter any given state that will achieve that reward. However, the upside down reinforcement learning method finds a set of actions that will result in a specific state that is associated with a reward. Upside down RL replaces the Q-function with a new function called the Behavior function.

Take aways and Criticisms

In the psuedo code implementation of ꓤꓤ, the authors adopt an algorithmic architecture that is very similar to supervised learning. They sample the replay buffer to train, choose actions based on the trained agent and continue this process until desired behaviour is achieved. This seems very simple and easy to understand when compared to training DQNs. However, it seems almost too good to be true. There are severe limitations to imitation learning that become evident in stochastic environments. I would worry that ꓤꓤ will perform much worse in environments where the state transitions are not deterministic like they are in the baselines that they tested. In summary, I think the method is cool and simple but perhaps it is too simple.

dp

November 10, 2020

1 Dynamic Programming (8 regular points + 4 extra credit points for both CS4803 and CS7643)

In this assignment, we will implement a few dynamic programming algorithms, namely, policy iteration and value iteration and run them on a simple MDP - the Frozen Lake environment.

The sub-routines for these algorithms are present in `vi_and_pi.py` and must be filled out to test your implementation.

The deliverables are located at the end of this notebook and show the point distrbution for each part.

Value iteration is worth 8 points of regular credit and policy iteration is worth 4 extra credit points for both sections of this course CS 7643 and CS 4803.

[1]:
```
%load_ext autoreload
%autoreload 2

import numpy as np
import gym
import time

from IPython.display import clear_output

from lake_envs import *
from vi_and_pi import *

np.set_printoptions(precision=3)

env_d = gym.make("Deterministic-4x4-FrozenLake-v0")
env_s = gym.make("Stochastic-4x4-FrozenLake-v0")
```

1.0.1 Render Mode

The variable `RENDER_ENV` is set `True` by default to allow you to see a rendering of the state of the environment at every time step. However, when you complete this assignment, you must set this to `False` and re-run all blocks of code. This is to prevent excessive amounts of rendered environments from being included in the final PDF.

IMPORTANT: SET `RENDER_ENV` TO FALSE BEFORE SUBMISSION!

[2]:
```
RENDER_ENV = False
```

1.1 Part 1: Value Iteration

For the first part, you will implement the familiar value iteration update from class.

In `vi_and_pi.pi` and complete the `value_iteration` function.

Run the cell below to train value iteration and render a single episode of following the policy obtained at the end of value iteration.

You should expect to get an Episode reward of `1.0`.

[4]:
```
print("\n" + "-"*25 + "\nBeginning Value Iteration\n" + "-"*25)

V_vi, p_vi = value_iteration(env_d.P, env_d.nS, env_d.nA, gamma=0.9, tol=1e-3)
render_single(env_d, p_vi, 100, show_rendering=RENDER_ENV)
```

```
-------------------------
Beginning Value Iteration
-------------------------
Episode reward: 1.000000
```

1.2 Part 2: Policy Iteration

This is a bonus question in which you will implement policy iteration. If you do not wish to attempt this bonus quesiton, skip to the next part.

In class, we studied the value iteration update:

$$V_{t+1}(s) \leftarrow \max_a \sum_{s'} p(s'|s,a) \left[r(s,a) + \gamma V_t(s') \right]$$

This is used to compute the value function V^* corresponding to the optimal policy π^*. We can alternatively compute the value function V^π corresponding to an arbitrary policy π, with a similar update loop:

$$V^\pi_{t+1}(s) \leftarrow \sum_a \pi(a|s) \sum_{s'} p(s'|s,a) \left[r(s,a) + \gamma V^\pi_t(s') \right]$$

On convergence, this will give us V^π, which is the first step of a policy iteration update.

The second step involves policy refinement, which will update the policy to take actions greedily with respect to V^π:

$$\pi_{new} \leftarrow \arg\max_a \left[r(s,a) + \gamma \sum_{s'} p(s'|s,a) V^\pi(s') \right]$$

A single update of policy iteration involves the two above steps: (1) policy evaluation (which itself is an inner loop which will converge to V^{π} and (2) policy refinement. In the first part of assignment, you will implement the functions for policy evaluation, policy improvement (refinement) and policy iteration.

In `vi_and_pi.pi` and complete the `policy_evaluation`, `policy_improvement` and `policy_iteration` functions. Run the blocks below to test your algorithm.

[5]:
```
####################################################
# Use this space for debugging                     #
# Make sure to delete this code before submission #
####################################################
pass
####################################################
```

[37]:
```
print("\n" + "-"*25 + "\nBeginning Policy Iteration\n" + "-"*25)

V_pi, p_pi = policy_iteration(env_d.P, env_d.nS, env_d.nA, gamma=0.9, tol=1e-3)
render_single(env_d, p_pi, 100, show_rendering=RENDER_ENV)
```

```
-------------------------
Beginning Policy Iteration
-------------------------
```

```
---------------------------------------------------------------------------
KeyboardInterrupt                         Traceback (most recent call last)
<ipython-input-37-56fd34704a30> in <module>

render_single(env_s, p_vi, 100, show_rendering=RENDER_ENV)
```

```
-------------------------
Beginning Value Iteration
-------------------------
Episode reward: 1.000000
```

1.4 Part 4: PI on Stochastic Frozen Lake

This is a bonus question to run policy iteration on stochastic frozen lake.

Now we will apply our implementation on an MDP where transitions to next states are stochastic. Modify your implementation of value iteration as needed so that policy iteration and value iteration work for stochastic transitions.

[40]:
```
####################################################
# Use this space for debugging                     #
# Make sure to delete this code before submission  #
####################################################
pass
####################################################
```

[41]:
```
print("\n" + "-"*25 + "\nBeginning Policy Iteration\n" + "-"*25)

V_pi, p_pi = policy_iteration(env_s.P, env_s.nS, env_s.nA, gamma=0.9, tol=1e-3)
render_single(env_s, p_pi, 100, show_rendering=RENDER_ENV)
```

```
-------------------------
Beginning Policy Iteration
-------------------------
Episode reward: 0.000000
```

1.5 Evaluate All Policies

Now, we will first test the value iteration implementation on two kinds of environments - the dererministic FrozenLake and the stochastic FrozenLake. We will also run the same for policy iteration

1.5.1 Deliverable 1 (4 points)

Run value iteration on deterministic FrozenLake. You should get a reward of 1.0 for full credit.

[8]:
```
print("\nValue Iteration on Deterministic FrozenLake:")
V_vi, p_vi = value_iteration(env_d.P, env_d.nS, env_d.nA, gamma=0.9, tol=1e-3)
evaluate(env_d, p_vi, max_steps=100, max_episodes=2)
```

```
Value Iteration on Deterministic FrozenLake:
> Average reward over 2 episodes:                       1.0
> Percentage of episodes goal reached:                  100%
```

1.5.2 Deliverable 2 (4 points)

Run value iteration on stochastic FrozenLake. Note that this time, running the same policy over multiple episodes will result in different outcomes (final reward) due to stochastic transitions in the environment, and even the optimal policy may not succeed in reaching the goal state 100% of the time.

You should get a reward of 0.7 or higher over 1000 episodes for full credit.

[9]:
```
print("\nValue Iteration on Stochastic FrozenLake:")
V_vi, p_vi = value_iteration(env_s.P, env_s.nS, env_s.nA, gamma=0.9, tol=1e-3)
evaluate(env_s, p_vi, max_steps=100, max_episodes=1000)
```

```
Value Iteration on Stochastic FrozenLake:
> Average reward over 1000 episodes:                    0.748
> Percentage of episodes goal reached:                  94%
```

1.5.3 Deliverable 3 (2 points. Extra Credit for both CS4803 and CS7643)

Run policy iteration on deterministic FrozenLake. You should get a reward of 1.0 for full credit.

[10]:
```
print("Policy Iteration on Deterministic FrozenLake:")
V_pi, p_pi = policy_iteration(env_d.P, env_d.nS, env_d.nA, gamma=0.9, tol=1e-3)
evaluate(env_d, p_pi, max_steps=100, max_episodes=2)
```

```
Policy Iteration on Deterministic FrozenLake:
> Average reward over 2 episodes:                       0.0
> Percentage of episodes goal reached:                  0%
```

1.5.4 Deliverable 4 (2 points. Extra Credit for both CS4803 and CS7643)

Run policy iteration on stochastic FrozenLake.

You should get a reward of 0.7 or higher over 1000 episodes for full credit.

[11]:
```
print("Policy Iteration on Stochastic FrozenLake:")
V_pi, p_pi = policy_iteration(env_s.P, env_s.nS, env_s.nA, gamma=0.9, tol=1e-3)
evaluate(env_s, p_pi, max_steps=100, max_episodes=1000)
```

```
Policy Iteration on Stochastic FrozenLake:
> Average reward over 1000 episodes:                    0.0
> Percentage of episodes goal reached:                  100%
```

1.6 Submission Reminder

PLEASE RE-RUN THE NOTEBOOK WITH `RENDER_ENV` SET TO FALSE BEFORE SUBMISSION!

q_learning

November 10, 2020

1 Q-Learning & DQNs (12 regular points + 2 extra credit points for both CS4803 and CS7643)

In this section, we will implement a few key parts of the Q-Learning algorithm for two cases - (1) A Q-network which is a single linear layer (referred to in RL literature as "Q-learning with linear function approximation") and (2) A deep (convolutional) Q-network, for some Atari game environments where the states are images.

Optional Readings: - **Playing Atari with Deep Reinforcement Learning**, Mnih et. al., https://www.cs.toronto.edu/~vmnih/docs/dqn.pdf - **The PyTorch DQN Tutorial** https://pytorch.org/tutorials/intermediate/reinforcement_q_learning.html

from utils.schedule import LinearExploration, LinearSchedule
from utils.preprocess import greyscale
from utils.wrappers import PreproWrapper, MaxAndSkipEnv

from linear_qnet import LinearQNet
from cnn_qnet import ConvQNet

if torch.cuda.is_available():
    device = torch.device('cuda', 0)
else:
    device = torch.device('cpu')
```

1.1 Part 1: Setup Q-Learning with Linear Function Approximation

Training Q-networks using (Deep) Q-learning involves a lot of moving parts. However, for this assignment, the scaffolding for the first 3 points listed below is provided in full and you must only complete point 4. You may skip to point 4 if you only care about the implementation required for this assignment.

1. **Environments**: We will use the standardized OpenAI Gym framework for environment API calls (read through http://gym.openai.com/docs/ if you want to know more details about this interface). Specifically, we will use a custom Test environment defined in `utils/test_env.py` for initial sanity checks and then Gym-Atari environments later on.

2. **Exploration**: In order to train any RL model, we require experience or "data" gathered from interacting with the environment by taking actions. What policy should we use to collect this experience? Given a Q-network, one may be tempted to define a greedy policy which always picks the highest valued action at every state. However, this strategy will in most cases not work since we may get stuck in a local minima and never explore new states in the environment which may lead to a better reward. Hence, for the purpose of gathering experience (or "data") from the environment, it is useful to follow a policy that deviates from the greedy policy slightly in order to explore new states. A common strategy used in RL is to follow an ϵ-greedy policy which with probability $0 < \epsilon < 1$ picks a random action instead of the action provided by the greedy policy.

3. **Replay Buffers**: Data gathered from a single trajectory of states and actions in the environment provides us with a batch of highly correlated (non IID) data, which leads to high variance in gradient updates and convergence. In order to ameliorate this, replay buffers are used to gather a set of transitions i.e. (state, action, reward, next state) tuples, by executing multiple trajectories in the environment. Now, for updating the Q-Network, we will first wait to fill up our replay buffer with a sufficiently large number of transitions over multiple different trajectories, and then randomly sample a batch of transitions to compute loss and update the models.

4. **Q-Learning network, loss and update**: Finally, we come to the part of Q-learning that we will implement for this assignment – the Q-network, loss function and update. In particular, we will implement a variant of Q-Learning called "Double Q-Learning", where we will maintain two Q networks – the first Q network is used to pick actions and the second "target" Q network is used to compute Q-values for the picked actions. Here is some referance material on the same - Blog 1, Blog 2, but we will not need to get into the details of Double Q-learning for this assignment. Now, let's walk through the steps required to implement this below.

    - **Linear Q-Network**: In `linear_qnet.py`, define the initialization and forward pass of a Q-network with a single linear layer which takes the state as input and outputs the Q-values for all actions.
    - **Setting up Q-Learning**: In `core/dqn_train.py`, complete the functions `process_state`, `forward_loss` and `update_step` and `update_target_params`. The loss function for our Q-Networks is defined for a single transition tuple of (state, action, reward, next state) as follows. $Q(s_t, a_t)$ refers to the state-action values computed by our first Q-network at the current state and and for the current actions, $Q_{target}(s_{t+1}, a_{t+1})$ refers to the state-action values for the next state and all possible future actions computed by the target

Q-Network

$$
\begin{aligned}
Q_{sample}(s_t) &= r_t \text{ if done} \\
&= r_t + \gamma \max_{a_{t+1}} Q_{target}\left(s_{t+1}, a_{t+1}\right) \text{ otherwise} \\
\text{Loss} &= \left(Q_{sample}(s_t) - Q(s_t, a_t)\right)^2
\end{aligned}
$$

1.1.1 Deliverable 1 (6 points)

Run the following block of code to train a Linear Q-Network. You should get an average reward of ~4.0, full credit will be given if average reward at the final evaluation is above 3.5

[2]:
```
from configs.p1_linear import config as config_lin

env = EnvTest((5, 5, 1))

# exploration strategy
exp_schedule = LinearExploration(env, config_lin.eps_begin,
        config_lin.eps_end, config_lin.eps_nsteps)

# learning rate schedule
lr_schedule  = LinearSchedule(config_lin.lr_begin, config_lin.lr_end,
        config_lin.lr_nsteps)

# train model
model = DQNTrain(LinearQNet, env, config_lin, device)
model.run(exp_schedule, lr_schedule)
```

Evaluating...

Average reward: 4.10 +/- 0.00
```

You should get a final average reward of over 4.0 on the test environment.

1.2 Part 2: Q-Learning with Deep Q-Networks

In `cnn_qnet.py`, implement the initialization and forward pass of a convolutional Q-network with architecture as described in this DeepMind paper:

"Playing Atari with Deep Reinforcement Learning", Mnih et. al. (https://www.cs.toronto.edu/~vmnih/docs/dqn.pdf)

1.2.1 Deliverable 2 (4 points)

Run the following block of code to train our Deep Q-Network. You should get an average reward of ~4.0, full credit will be given if average reward at the final evaluation is above 3.5

[6]:
```
from configs.p2_cnn import config as config_cnn

env = EnvTest((80, 80, 1))

# exploration strategy
exp_schedule = LinearExploration(env, config_cnn.eps_begin,
        config_cnn.eps_end, config_cnn.eps_nsteps)

# learning rate schedule
lr_schedule  = LinearSchedule(config_cnn.lr_begin, config_cnn.lr_end,
        config_cnn.lr_nsteps)

# train model
model = DQNTrain(ConvQNet, env, config_cnn, device)
model.run(exp_schedule, lr_schedule)
```

```

You should get a final average reward of over 4.0 on the test environment, similar to the previous case.

1.3 Part 3: Playing Atari Games from Pixels - using Linear Function Approximation

Now that we have setup our Q-Learning algorithm and tested it on a simple test environment, we will shift to a harder environment - an Atari 2600 game from OpenAI Gym: Pong-v0 (https://gym.openai.com/envs/Pong-v0/), where we will use RGB images of the game screen as our observations for state.

No additional implementation is required for this part, just run the block of code below (will take around 1 hour to train). We don't expect a simple linear Q-network to do well on such a hard environment - full credit will be given simply for running the training to completion irrespective of the final average reward obtained.

You may edit `configs/p3_train_atari_linear.py` if you wish to play around with hyperparamters for improving performance of the linear Q-network on Pong-v0, or try another Atari environment by changing the `env_name` hyperparameter. The list of all Gym Atari environments are available here: https://gym.openai.com/envs/#atari

1.3.1 Deliverable 3 (2 points)

Run the following block of code to train a linear Q-network on Atari Pong-v0. We don't expect the linear Q-Network to learn anything meaingful so full credit will be given for simply running this training to completion (without errors), irrespective of the final average reward.

[30]:
```
from configs.p3_train_atari_linear import config as config_lina

# make env
env = gym.make(config_lina.env_name)
env = MaxAndSkipEnv(env, skip=config_lina.skip_frame)
env = PreproWrapper(env, prepro=greyscale, shape=(80, 80, 1),
                    overwrite_render=config_lina.overwrite_render)

# exploration strategy
```

```
exp_schedule = LinearExploration(env, config_lina.eps_begin,
        config_lina.eps_end, config_lina.eps_nsteps)

# learning rate schedule
lr_schedule  = LinearSchedule(config_lina.lr_begin, config_lina.lr_end,
        config_lina.lr_nsteps)

# train model
model = DQNTrain(LinearQNet, env, config_lina, device)
print("Linear Q-Net Architecture:\n", model.q_net)
model.run(exp_schedule, lr_schedule)
```

```
Evaluating...

Linear Q-Net Architecture:

0.0001

- Training done.
Evaluating...

Average reward: -20.38 +/- 0.10
```

1.4 Part 4: Playing Atari Games from Pixels - using Deep Q-Networks

This part is extra credit and worth 5 bonus points. We will now train our deep Q-Network from Part 2 on Pong-v0.

Again, no additional implementation is required but you may wish to tweak your CNN architecture in `cnn_qnet.py` and hyperparameters in `configs/p4_train_atari_cnn.py` (however, evaluation will be considered at no farther than the default 5 million steps, so you are not allowed to train for longer). Please note that this training may take a very long time (we tested this on a single GPU and it took around 6 hours).

The bonus points for this question will be allotted based on the best evaluation average reward (EAR) before 5 million time stpes:

1. EAR >= 0.0 : 4/4 points
2. EAR >= -5.0 : 3/4 points
3. EAR >= -10.0 : 3/4 points
4. EAR >= -15.0 : 1/4 points

1.4.1 Deliverable 4: (2 points. Extra Credit for both CS4803 and CS7643)

Run the following block of code to train your DQN:

[ ]:
```
from configs.p4_train_atari_cnn import config as config_cnna

# make env
env = gym.make(config_cnna.env_name)
env = MaxAndSkipEnv(env, skip=config_cnna.skip_frame)
env = PreproWrapper(env, prepro=greyscale, shape=(80, 80, 1),
                    overwrite_render=config_cnna.overwrite_render)

# exploration strategy
exp_schedule = LinearExploration(env, config_cnna.eps_begin,
        config_cnna.eps_end, config_cnna.eps_nsteps)

# learning rate schedule
lr_schedule  = LinearSchedule(config_cnna.lr_begin, config_cnna.lr_end,
        config_cnna.lr_nsteps)

# train model
model = DQNTrain(ConvQNet, env, config_cnna, device)
print("CNN Q-Net Architecture:\n", model.q_net)
model.run(exp_schedule, lr_schedule)
```
